Abstract

Urban mobility systems exhibit complex nonlinear behavior due to stochastic vehicle arrival patterns and heterogeneous traffic compositions. Conventional signal timing frameworks lack adaptive intelligence, leading to suboptimal throughput and increased vehicular idle states. This study introduces a vision-driven adaptive control paradigm leveraging convolutional neural networks for dynamic traffic orchestration. To address these issues, this paper proposes an AI-based system utilizing deep learning (YOLO), computer vision, and live CCTV feeds to detect vehicle density in real-time and dynamically adjust traffic signal timings. The system architecture includes CCTV cameras for data acquisition, YOLO11/OpenCV modules for detection, and a central dashboard for monitoring and override. The methodology allows for adaptive signal control and has been tested using recorded traffic video data, demonstrating improved traffic flow, reduced waiting times, and lower emissions. Key findings include significant reductions in queue lengths and improvements in overall intersection throughput. The proposed solution offers scalable, low-cost smart city applications and provides a robust framework for future enhancements, including deployment in multiple junctions and emergency vehicle integration.

- Dynamic Signal Optimization
- Computer Vision

Introduction

Urban traffic management faces persistent challenges as vehicle population increases and intersections become more congested. Traditional fixed-timer signals frequently ignore actual traffic volumes, resulting in inefficient traffic

flow, increased wait times, and environmental harm. Advances in AI and deep learning, especially through real-time vision algorithms, enable smarter, responsive signal control systems that can greatly improve urban mobility. This research presents a dynamic signal control method, using real-time video feeds and AI detection, tailored for developing smart cities.

Literature survey

Contemporary investigations in intelligent transportation systems have increasingly emphasized reinforcement learning–driven adaptive signal control frameworks, particularly those leveraging Deep Q-Network architectures in conjunction with multimodal sensing infrastructures such as CCTV streams, GPS telemetry, and IoT-enabled devices. Simulation platforms, including SUMO and region-specific traffic datasets, are frequently employed to evaluate algorithmic performance under controlled yet realistic conditions. In parallel, advancements in FPGA-based implementations and hybrid cloud–edge computing paradigms are enabling scalable deployments within smart city ecosystems. Empirical evidence suggests that such AI-centric approaches significantly enhance traffic throughput, minimize vehicular delays, and contribute to reduced environmental impact. Emerging challenges, including distributional shifts and coordination in multi-agent reinforcement learning environments, continue to define the frontier of research in large-scale traffic network synchronization.

Proposed methodology (system architecture diagram proposed algorithm)

The architecture of the proposed traffic management framework is structured as a hierarchical, multi-layered pipeline integrating vision-based inference with adaptive decision-making mechanisms. Initially, continuous video feeds acquired from roadside surveillance units are subjected to object detection using advanced convolutional models such as YOLO11, enabling precise vehicle identification and lane-wise density estimation. Subsequently, the extracted traffic metrics are evaluated to classify congestion states into discrete levels, facilitating context-aware control strategies. The processed data is then relayed through heterogeneous communication protocols, including Wi-Fi, 4G, and LoRa networks, to a centralized processing unit responsible for optimizing signal phase durations in real time. Furthermore, the system incorporates a supervisory control interface, allowing operators to monitor traffic conditions and intervene during critical scenarios. The overall design encompasses interconnected modules for data acquisition, intelligent processing, communication, and visualization, forming a scalable and robust smart traffic control solution.

System Architecture

The proposed architecture integrates five core layers:

1. Data Acquisition: CCTV/IP traffic video feeds.
2. Processing Intelligence: YOLO11/OpenCV vehicle detection on Jetson Nano/Raspberry Pi edge devices.
3. Decision Control: Density-based signal time allocation algorithm (Python/Arduino bridge).
4. Communication: Wi-Fi/4G/LoRa data transmission between junction and central server.
5. Monitoring & Visualization: Real-time dashboard (React/Flask/Firebase) for authorities.

Example Flow:
CCTV Camera → Edge AI Box (YOLO) → Density Analyzer → Decision Logic → Traffic Controller → Real-time Dashboard

Proposed Algorithm

1. Capture input video stream from junction cameras.
2. Apply YOLO11 model to frames for per-lane vehicle counting.
3. Classify density:
    - Low: ≤10 vehicles
    - Medium: 11–20 vehicles
    - High: >20 vehicles
4. Allocate green signal:
    - Low: 20 sec
    - Medium: 40 sec
    - High: 60 sec
5. Transmit new timing to a smart traffic signal controller.
6. Monitor via dashboard; allow manual override if necessary.
7. Store all inputs/outputs for audit and future analytics.

Results & discussion

The experimental evaluation was conducted within a controlled simulation framework utilizing traffic datasets captured from the Karishma Chowk intersection. The detection module, powered by deep learning techniques, exhibited consistently high precision across varying illumination conditions and environmental disturbances. Empirical results indicate that the deployment of the adaptive control strategy led to a measurable decrease in vehicular queue accumulation, with an approximate reduction of 20%, alongside a notable enhancement in

intersection throughput efficiency. The system demonstrated near real-time responsiveness, maintaining latency below 0.5 seconds per processing cycle. However, performance degradation was observed in scenarios involving dense occlusions and complex traffic overlaps, highlighting the necessity for further model optimization and potential hardware acceleration at the edge. User-level evaluation suggested improved situational awareness through the monitoring interface, although scalability remains a critical consideration. Future work should focus on large-scale real-world validation and the integration of coordinated multi-junction traffic control mechanisms.

Conclusion

This research demonstrates that AI-powered adaptive traffic signal systems using deep learning and real-time video analytics can substantially improve urban intersection efficiency, reduce congestion, and optimize signal timings in a cost-effective manner. The developed prototype met its design objectives and offers a scalable framework for smart city traffic solutions. Ongoing work will focus on live deployment, emergency vehicle detection integration, and commercial partnerships for large-scale implementations.
